

User Personas

The two most common types of users of the Adaptive English Learning Application are students and teachers/coordinators. Both types of users have different purposes and environments. Students will typically be foreign English speakers with varying levels of education and exposure to English from various parts of the English-speaking world with the desire to improve proficiency for either personal or work-related reasons. They will be accessing the application either from a mobile device or a browser with varying levels of expertise from beginner to advanced. The chief characteristic of these students is that they will require bite-sized, entertaining, and personalized learning sessions since most of the students will be accessing the application for maximum learnable periods of a few minutes at a time at most. The system will have to incorporate varying difficulty levels from the backend.

An example of a learner persona could be the following: Amina is a 21-year-old university student whose mother tongue is Arabic; she is learning English to improve her academic writing and reading skills. She uses mostly her smartphone version of the program for short study sessions between classes or at home in the evening. She often struggles with academic vocabulary and grammatical accuracy, and whenever she encounters new sentence structures, she relies on immediate explanations and translations. The backend for this persona must be able to deliver on-demand AI-powered explanations faster, track consistent progress across multiple short sessions, and recommend sets of adaptive exercises based on her performance.

The second user persona is represented by teachers or coordinators who are involved in more organized learning settings such as training rooms, schools, or organized learning groups. They primarily need to monitor the learners' performance, identify areas where learners are struggling, and help those learners by using insights gleaned from the data. For organized network setups, the teacher typically engages with the learning system via a web portal where they review learner collective performance metrics, engagement metrics, as well as learner progress predictors. But for the backend, handling enormous amounts of data for learners, role-based management, and generating accurate analytical data is a necessity in the learning environment. The backend can be designed for both personalized learning experiences as well as intelligent learning management by identifying these user personas precisely in a learning context.

An example of a teacher persona could be the following: Mr. Daniel is a 38-year-old English teacher in-charge of a pool of adult learning in a language training institution. He is a teacher role model. During office hours, Mr. Daniel relies on a desktop web browser for system access, employing the teacher dashboard in analyzing deficiencies

in topics, engagement, and completion levels. Mr. Daniel relies on analytics data to identify learning deficiencies among some of the learning pupils, adjusting the topics of the class in relation to analysis data. The backend system for Mr. Daniel has the responsibility of gathering data, ensuring safety in role-defined access, and providing accurate analytics data in decision-making.
